

ZigBee is a Personal Area Network task group with low rate task group 4. It is a technology of home networking. ZigBee is a technological standard created for controlling and sensing the network. As we know that ZigBee is the Personal Area Network of task group 4 so it is based on IEEE 802.15.4 and is created by Zigbee Alliance.

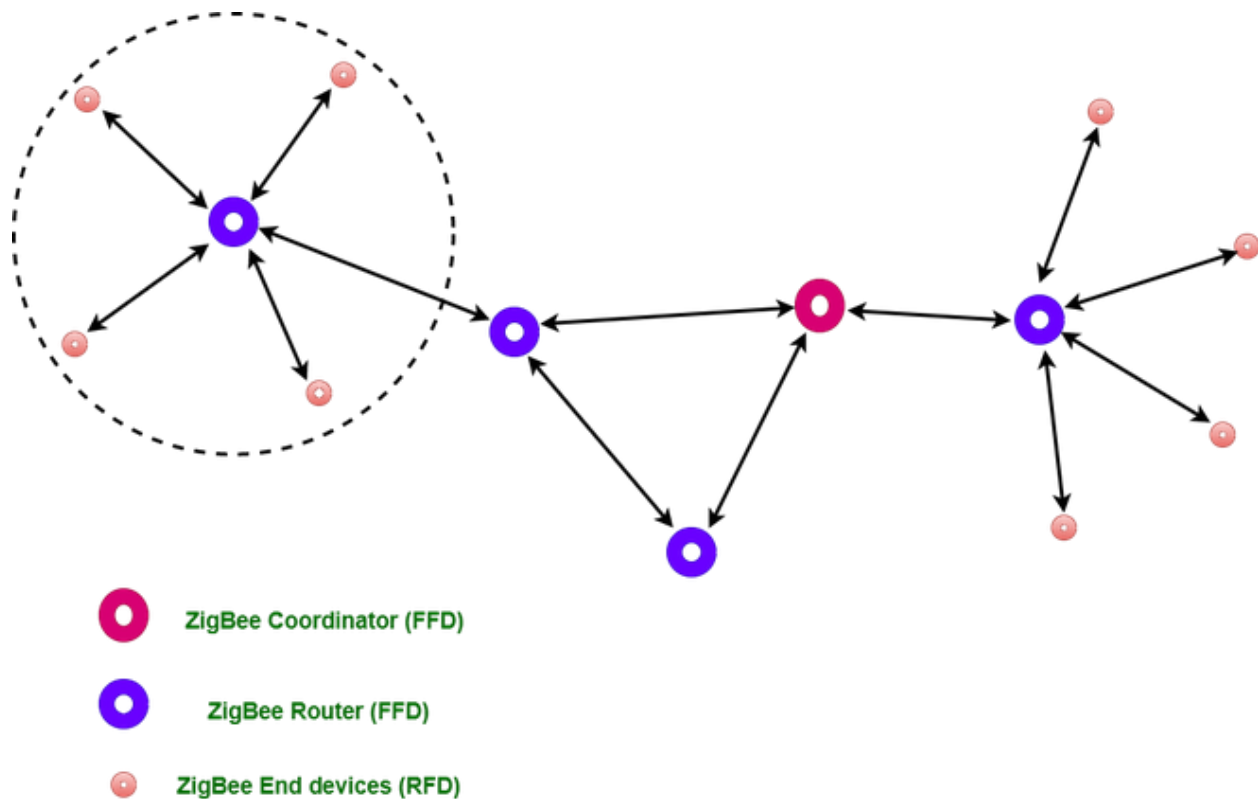

ZigBee is an open, global, packet-based protocol designed to provide an easy-to-use architecture for secure, reliable, low power wireless networks. Flow or process control equipment can be placed anywhere and still communicate with the rest of the system. It can also be moved, since the network doesn't care about the physical location of a sensor, pump or valve.

ZigBee is a standard that addresses the need for very low-cost implementation of Low power devices with Low data rates for short-range wireless communications.

IEEE 802.15.4 supports star and peer-to-peer topologies. The ZigBee specification supports star and two kinds of peer-to-peer topologies, mesh and cluster tree. ZigBee-compliant devices are sometimes specified as supporting point-to-point and point-to-multipoint topologies.

Types of ZigBee Devices:

- **Zigbee Coordinator Device:** It communicates with routers. This device is used for connecting the devices.
- **Zigbee Router:** It is used for passing the data between devices.
- **Zigbee End Device:** It is the device that is going to be controlled.

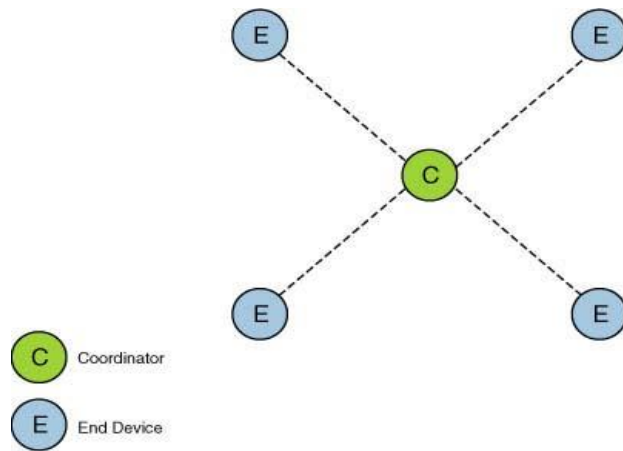

Zigbee Network Topology: Exploring the Three Types

Network topology plays a crucial role in the design and functionality of communication networks. It encompasses the arrangement and interconnection of elements such as links and nodes within a network.

In the context of Zigbee, a wireless communication protocol widely used in IoT (Internet of Things) applications.

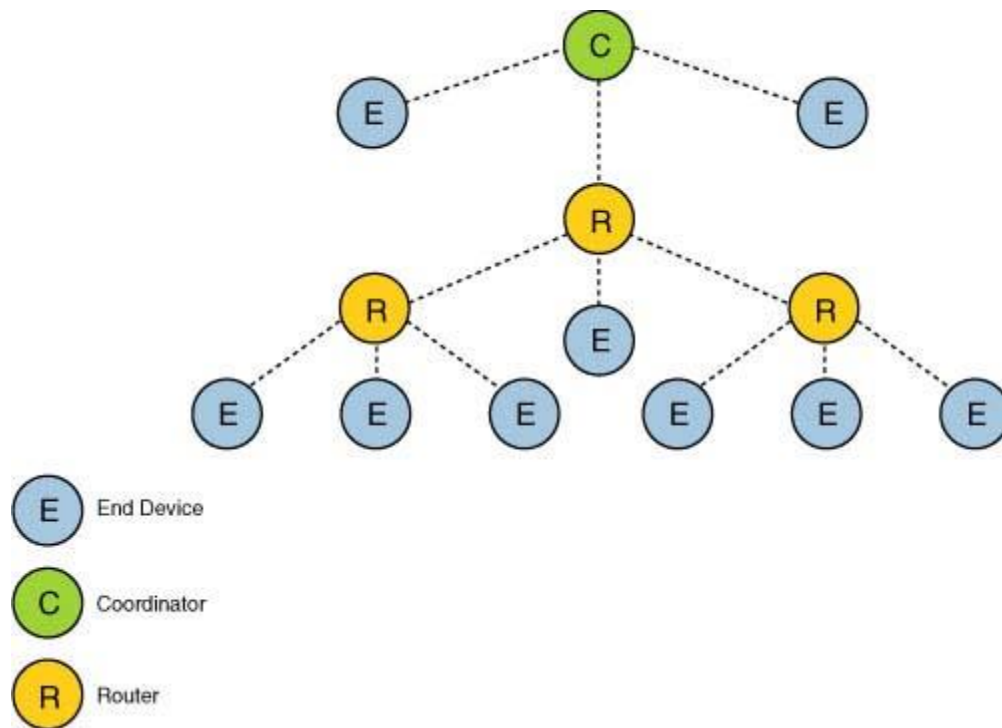

There are three main types of network topology: star topology, tree topology, and peer-to-peer or mesh topology.

Each of these topologies influences how messages are routed and which devices are connected to one another. In this article, we will delve deeper into each of these Zigbee network topologies to gain a comprehensive understanding of their characteristics and implications.

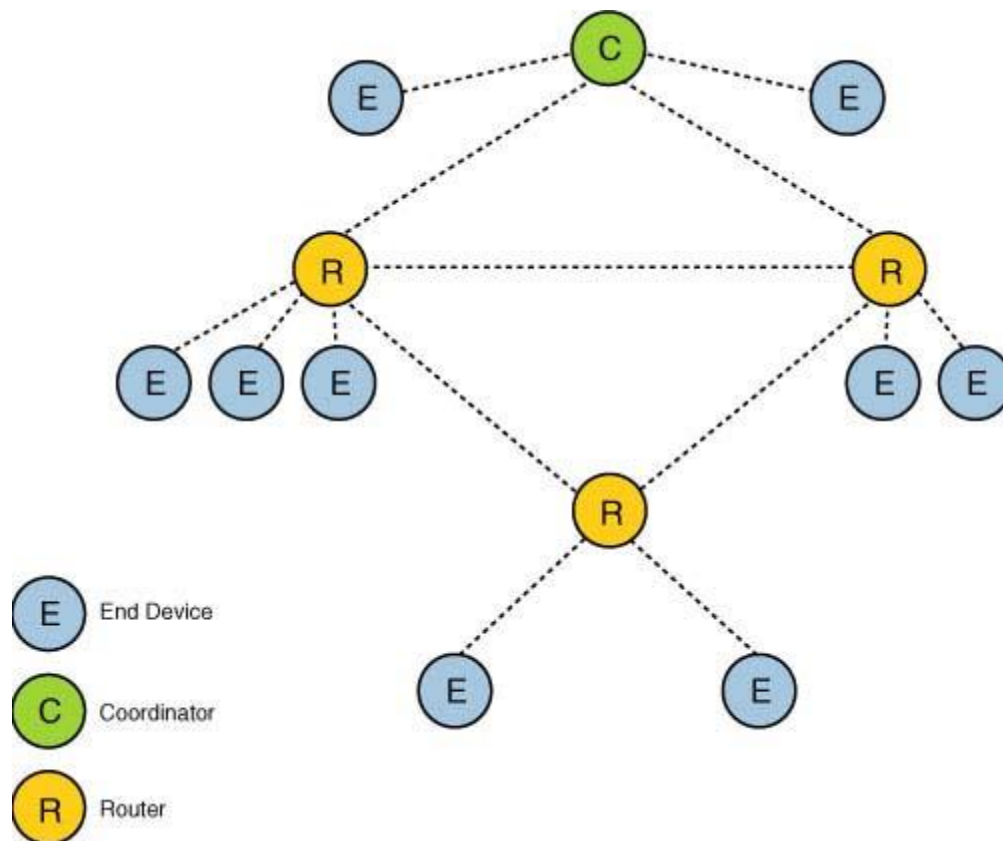

Star Topology

The first Zigbee network topology we will explore is the star topology. As its name suggests, this topology resembles a star-shaped structure, with a central coordinator node and several end devices connected to it. The star topology is the simplest and most basic configuration within the Zigbee network. In fact, it is defined by the underlying 802.15.4 specification, which serves as the foundation for the Zigbee protocol. In this setup, all communication between devices flows through the coordinator node. While the star topology offers simplicity and ease of implementation, it also presents limitations. Since all communication relies on the coordinator, a failure in this central node can disrupt the entire network. Additionally, there is no alternative path for message transmission from the source to the end devices, which can become a hindrance in certain scenarios.

Tree Topology

Moving on, let us explore the tree topology, which builds upon the star topology by introducing additional elements and complexity. In the tree topology, we still have a coordinator node, but it is accompanied by a few routers and end devices. The coordinator or routers function as central nodes or root nodes within the network, while the end devices are referred to as children. These children devices can only communicate with their parent node, whether it is a coordinator or a router. Routers play a crucial role in extending the network coverage, allowing devices that are distant from the coordinator to connect and communicate effectively. However, one limitation of the tree topology is that if the parent node becomes disabled or encounters a failure, the children nodes connected to it will be unable to communicate with other devices in the network, even if they are physically close to each other. This dependency on a single parent node can lead to network isolation and limited connectivity.

Mesh Topology

Finally, we come to the peer-to-peer or mesh topology, the most versatile and resilient of the three Zigbee network topologies. In a mesh topology, we have a coordinator, several routers, and end devices, similar to the tree topology. However, the key differentiating factor is the presence of multiple potential paths for message transmission. Each device in the mesh network can communicate with any other device, creating a web-like structure. This flexibility allows for increased network range, as additional devices can be added to expand the coverage area. Furthermore, if a transmission path fails or becomes obstructed, the affected node can dynamically find an alternate path to reach its destination, thereby eliminating dead zones within the network. This self-healing capability enhances the reliability and robustness of the Zigbee network. Moreover, the mesh topology simplifies the process of adding or removing devices from the network since any device can communicate with any destination device within the network. This flexibility and scalability make the mesh topology highly suitable for IoT applications where device composition and connectivity requirements may change frequently.

General Characteristics of Zigbee Standard:

- Low Power Consumption
- Low Data Rate (20- 250 kbps)
- Short-Range (75-100 meters)
- Network Join Time (~ 30 msec)
- Support Small and Large Networks (up to 65000 devices (Theory); 240 devices (Practically))
- Low Cost of Products and Cheap Implementation (Open Source Protocol)
- Extremely low-duty cycle.
- 3 frequency bands with 27 channels.

Operating Frequency Bands (Only one channel will be selected for use in a network):

1. **Channel 0:** 868 MHz (Europe)
2. **Channel 1-10:** 915 MHz (the US and Australia)
3. **Channel 11-26:** 2.4 GHz (Across the World)

Features of Zigbee:

1. **Stochastic addressing:** A device is assigned a random address and announced. Mechanism for address conflict resolution. Parents node don't need to maintain assigned address table.
2. **Link Management:** Each node maintains quality of links to neighbors. Link quality is used as link cost in routing.
3. **Frequency Agility:** Nodes experience interference report to channel manager, which then selects another channel
4. **Asymmetric Link:** Each node has different transmit power and sensitivity. Paths may be asymmetric.
5. **Power Management:** Routers and Coordinators use main power. End Devices use batteries.

Advantages of Zigbee:

1. Designed for low power consumption.
2. Provides network security and application support services operating on the top of IEEE.
3. Zigbee makes possible completely networks homes where all devices are able to communicate and be
4. Use in smart home
5. Easy implementation
6. Adequate security features.
7. **Low cost:** Zigbee chips and modules are relatively inexpensive, which makes it a cost-effective solution for IoT applications.
8. **Mesh networking:** Zigbee uses a mesh network topology, which allows for devices to communicate with each other without the need for a central hub or router. This makes it ideal for use in smart home applications where devices need to communicate with each other and with a central control hub.
9. **Reliability:** Zigbee protocol is designed to be highly reliable, with robust mechanisms in place to ensure that data is delivered reliably even in adverse conditions.

Disadvantages of Zigbee :

1. **Limited range:** Zigbee has a relatively short range compared to other wireless communications protocols, which can make it less suitable for certain types of applications or for use in large buildings.
2. **Limited data rate:** Zigbee is designed for low-data-rate applications, which can make it less suitable for applications that require high-speed data transfer.
3. **Interoperability:** Zigbee is not as widely adopted as other IoT protocols, which can make it difficult to find devices that are compatible with each other.
4. **Security:** Zigbee's security features are not as robust as other IoT protocols, making it more vulnerable to hacking and other security threats.

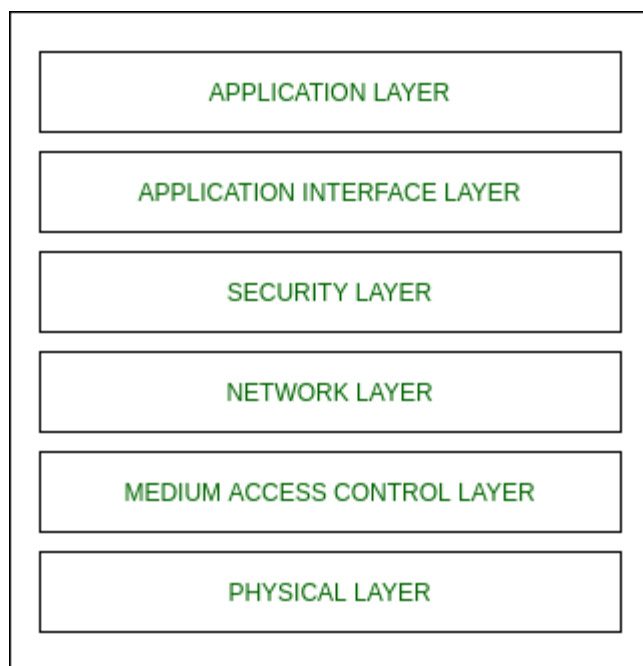

Zigbee Network Topologies:

- **Star Topology** (ZigBee Smart Energy): Consists of a coordinator and several end devices, end devices communicate only with the coordinator.
- **Mesh Topology** (Self Healing Process): Mesh topology consists of one coordinator, several routers, and end devices.
- **Tree Topology**: In this topology, the network consists of a central node which is a coordinator, several routers, and end devices. the function of the router is to extend the network coverage.

Architecture of Zigbee:

Zigbee architecture is a combination of 6 layers.

1. Application Layer
2. Application Interface Layer
3. Security Layer
4. Network Layer
5. Medium Access Control Layer
6. Physical Layer

- **Physical layer:** The lowest two layers i.e the physical and the MAC (Medium Access Control) Layer are defined by the IEEE 802.15.4 specifications. The Physical layer is closest to the hardware and directly controls and communicates with the Zigbee radio. The physical layer translates the data packets in the over-the-air bits for transmission and vice-versa during the reception.
- **Medium Access Control layer (MAC layer):** The layer is responsible for the interface between the physical and network layer. The MAC layer is also responsible for providing PAN ID and also network discovery through beacon requests.
- **Network layer:** This layer acts as an interface between the MAC layer and the application layer. It is responsible for mesh networking.
- **Application layer:** The application layer in the Zigbee stack is the highest protocol layer and it consists of the application support sub-layer and Zigbee device object. It contains manufacturer-defined applications.

Channel Access:

1. **Contention Based Method** (Carrier-Sense Multiple Access With Collision Avoidance Mechanism)
2. **Contention Free Method** (Coordinator dedicates a specific time slot to each device (Guaranteed Time Slot (GTS)))

Zigbee Applications:

1. Home Automation
2. Medical Data Collection
3. Industrial Control Systems
4. meter reading system
5. light control system
6. Commercial
7. Government Markets Worldwide
8. Home Networking

ZigBee is a communication protocol often used in wireless sensor networks and IoT applications. Here are some mathematical questions related to ZigBee:

Data Rate Calculation: If a ZigBee network operates at a symbol rate of 250 ksymbols/s using O-QPSK modulation, and each symbol represents 2 bits of data, what is the effective data rate in bits per second?

Data Rate Calculation:

- **Formula:** Data rate (bits/s) = Symbol rate (symbols/s) * Bits per symbol
- **Values:**
 - Symbol rate = 250 ksymbols/s = 250,000 symbols/s
 - O-QPSK modulation = 2 bits per symbol
- **Calculation:**
 - Data rate = 250,000 symbols/s * 2 bits/symbol = 500,000 bits/s

Path Loss Calculation: In a ZigBee network, the transmitted signal power is 5 mW, and the received signal power at a distance of 10 meters is measured to be 50 μ W. What is the path loss in decibels (dB)?

Path Loss Calculation:

Path Loss Model: We'll use the **Free Space Path Loss Model** as it's a simple model for open spaces like buildings with minimal obstructions. However, in practice, buildings can introduce additional path loss, so the actual value might be higher.

- **Formula:** Path loss (dB) = $20 * \log_{10}(d) + 20 * \log_{10}(f) - 147.55$
- **Values:**
 - Distance (d) = 10 meters
 - Frequency (f) = 2.4 GHz (ZigBee operates in the 2.4 GHz ISM band)
- **Calculation:**
 - Path loss = $20 * \log_{10}(10) + 20 * \log_{10}(2.4 \times 10^9) - 147.55$
 - Path loss ≈ 81.1 dB

Channel Allocation: In a ZigBee network with 16 available channels operating in the 2.4 GHz ISM band, if each channel has a bandwidth of 5 MHz, how much total bandwidth is available for communication?

Total Bandwidth Calculation:

- **Formula:** Total bandwidth (MHz) = Number of channels * Bandwidth per channel
- **Values:**
 - Number of channels = 16
 - Bandwidth per channel = 5 MHz
- **Calculation:**

- Total bandwidth = 16 channels * 5 MHz/channel = 80 MHz

Packet Error Rate (PER): In a ZigBee network, if the PER is measured to be 0.01, meaning that 1% of transmitted packets are received with errors, and the network sends 100 packets per second, how many packets are received successfully per second?

Packet Reception Rate Calculation:

- **Success Rate:** $1 - \text{PER}$ (Packet Error Rate)
- **Values:**
 - PER = 0.01
 - Packets sent per second = 100
- **Calculation:**
 - Success rate = $1 - 0.01 = 0.99$
 - Packets received successfully per second = Success rate * Packets sent per second
 - Packets received successfully = $0.99 * 100 \text{ packets/s} = 99 \text{ packets/s}$

Propagation Delay: If the speed of propagation of electromagnetic waves in air is approximately 3×10^8 meters per second, and a ZigBee signal travels a distance of 100 meters, what is the propagation delay in microseconds?

Propagation Delay Calculation:

- **Formula:** Propagation delay (seconds) = Distance (meters) / Speed of propagation (meters/second)
- **Values:**
 - Distance = 100 meters
 - Speed of propagation = 3×10^8 meters/second
- **Calculation:**
 - Propagation delay = $100 \text{ meters} / (3 \times 10^8 \text{ meters/second})$
 - Propagation delay $\approx 3.33 \times 10^{-7}$ seconds
 - Convert to microseconds: $3.33 \times 10^{-7} \text{ seconds} * 10^6 \text{ microseconds/second} = 0.333 \text{ microseconds}$

Network Topology: In a ZigBee mesh network with 10 nodes, each node can directly communicate with at most 3 neighboring nodes. What is the maximum number of simultaneous communication links possible in this network?

Maximum Communication Links:

- In a mesh network, each node can connect to **at most 3 neighboring nodes**.
- With 10 nodes, each can connect to 3 others, but these connections might overlap (e.g., node A connecting to node B and node B connecting to node A are counted twice).

- Therefore, the **maximum number of simultaneous communication links** is not simply $10 \text{ nodes} * 3 \text{ connections/node} = 30$.

To calculate the exact number, we would need to consider the specific network topology and connections between nodes.

Channel Interference: If two ZigBee networks operating in the same vicinity use overlapping channels, such that Network A uses channels 15, 16, and 17, while Network B uses channels 16, 17, and 18, how much interference can Network B cause to Network A?

In a mesh network, nodes can communicate with multiple neighbors simultaneously, but the total number of concurrent links is limited due to factors like channel access and potential interference.

Given:

- 10 nodes
- Each node can connect to at most 3 neighbors

Calculation:

1. **Consider each node and its connections:**
 - Each node can have a maximum of 3 outgoing links to its neighbors.
 - However, these same neighboring nodes can also have outgoing links to other nodes in the network.
2. **Avoid double-counting connections:**
 - To avoid counting the same link twice (once for each node involved), consider only the outgoing links from each node.
3. **Maximum outgoing links:**
 - Since each node can have 3 outgoing links, the total number of outgoing links from all 10 nodes is:
 - Total outgoing links = Nodes * Links per node
 - Total outgoing links = $10 \text{ nodes} * 3 \text{ links/node} = 30 \text{ links}$

Therefore, the maximum number of simultaneous communication links possible in this network is 30.

Wi-Fi stands for Wireless Fidelity, and it is developed by an organization called IEEE (Institute of Electrical and Electronics Engineers) they set standards for the Wi-Fi system.

Each Wi-Fi network standard has two parameters :

1. **Speed** –
This is the data transfer rate of the network measured in Mbps (1 megabit per second).
2. **Frequency** –
On what radio frequency, the network is carried on. Two bands of frequency for the Wi-Fi are 2.4 GHz and 5 GHz. In short, it is the frequency of radio wave that carries data.

Two Frequencies of Wi-Fi signal :

Wi-Fi routers that come with 2.4 GHz or 5 GHz are called the single-band routers but a lot of new routers support both 2.4 GHz and 5 GHz frequency they are called dual-band routers.

The 2.4 GHz is a common Wi-Fi band, but it is also used by other appliances like Bluetooth devices, wireless phones, cameras, etc. Because of the signal used by so many devices, the signal becomes overcrowded and speed becomes slow. So 5 GHz comes into the picture, It is new, and not commonly used, and because it is used by fewer devices there is no signal crowding and interference.

The 2.4 GHz transmits data at a slower speed than 5 GHz but does have a longer range than 5 GHz. The 5 GHz transmits data at a faster rate, but it has a shorter range because it has a higher frequency.

Parameter	2.4 GHz	5 GHz
Speed	Comparatively Low	High
Range	High	Comparatively low

Different standards of Wi-Fi :

These are the Wi-Fi standards that evolved from 1997 to 2021. In 1997 IEEE created one standard and gave the name 802.11.

IEEE 802.11 –

1. It was developed in 1997.
2. Speed is about 2 Mbps (2 megabits per second).

IEEE 802.11a –

1. This standard is developed in 1999.
2. 802.11a is useful for commercial and industrial purposes.
3. It works on a 5 GHz frequency.

4. The maximum speed of 802.11a is 54 Mbps.
5. This standard was made to avoid interference with other devices which use the 2.4 GHz band.

IEEE 802.11b –

1. This standard also created with 802.11a in 1999.
2. The difference is that it uses a 2.4 GHz frequency band.
3. The speed of 802.11b is 11 Mbps.
4. This standard is useful for home and domestic use.

IEEE 802.11g –

1. This standard is designed in 2003.
2. Basically, it has combined the properties of both 802.11a and 802.11b.
3. The frequency band used in this is 2.4 GHz for better coverage.
4. And the maximum speed is also up to 54 Mbps.

IEEE 802.11n –

1. This was introduced in 2009.
2. 802.11n operates on both 2.4 GHz and 5 GHz frequency bands, they are operated individually.
3. The data transfer rate is around 600 Mbps.

IEEE 802.11ac –

1. This standard is developed in 2013 named 802.11ac.
2. Wi-Fi 802.11ac works on the 5 GHz band.
3. The maximum speed of this standard is 1.3 Gbps.
4. It gives less range because of the 5 GHz band, but nowadays most of the devices are working on 802.11n and 802.11ac standards.

IEEE 802.11ax –

1. It is the newest and advanced version of Wi-Fi.
2. This is released in 2019.
3. Operates on both 2.4 GHz and 5 GHz for better coverage as well as better speed.
4. User will get 10 Gbps of maximum speed around 30-40 % improvement over 802.11ac

Tabular Representation :

Version	Introduced in	Frequency band used	Maximum speed provided
IEEE 802.11a	1999	5 GHz	54 Mbps
IEEE 802.11b	1999	2.4 GHz	11 Mbps
IEEE 802.11g	2003	2.4 GHz	54 Mbps
IEEE 802.11n	2009	Both 2.4 GHz and 5 GHz	600 Mbps
IEEE 802.11ac	2013	5 GHz	1.3 Gbps
IEEE 802.11ax	2019	Both 2.4 GHz and 5 GHz	Up to 10 Gbps

Now recently Wi-Fi alliance announced the new naming scheme for Wi-Fi standards. Rather than the complex names like “**802.11b**” name now we can call as “**Wi-Fi 1**”, and similar for others. This will help consumers for easy to understand as 802.11 is difficult to understand.

New Naming Standards :

Network	Wi-Fi Standard
IEEE 802.11b	Wi-Fi 1
IEEE 802.11a	Wi-Fi 2
IEEE 802.11g	Wi-Fi 3
IEEE 802.11n	Wi-Fi 4
IEEE 802.11ac	Wi-Fi 5
IEEE 802.11ax	Wi-Fi 6

This is all about Wi-Fi and its various versions, In the future also, we may get a lot of improvements in the Wi-Fi system in speed and large range also.

Scenario: A Wi-Fi network operates in the 5 GHz band using the 802.11ac standard and experiences a path loss of 60 dB at a distance of 10 meters. The transmitted power is 20 mW, and the receiver sensitivity is -80 dBm.

Reference Book: "Wi-Fi: The Complete Guide" by Matthew Gast (Refer to relevant sections on path loss, signal strength, and data rates for 802.11ac)

Questions:

1. **Received Signal Strength:**

- Calculate the received signal strength (RSSI) in dBm at a distance of 10 meters.

2. **Maximum Range:**

- Estimate the maximum range of the network where the received signal strength meets the receiver sensitivity.

3. **Data Rate:**

- If the network uses 256-QAM modulation and a channel width of 80 MHz, what is the theoretical maximum data rate in Mbps?

Answers:

1. **Received Signal Strength (RSSI):**

Formula: Received power (dBm) = Transmitted power (dBm) - Path loss (dB)

Values:

- Transmitted power (dBm) = $10 * \log_{10}(20 \text{ mW}) = 13 \text{ dBm}$ (convert mW to dBm)
- Path loss (dB) = 60 dB

Calculation:

- Received power (dBm) = $13 \text{ dBm} - 60 \text{ dB} = -47 \text{ dBm}$

Therefore, the received signal strength (RSSI) at 10 meters is -47 dBm.

2. **Maximum Range:**

Concept: We need to find the distance where the received power equals the receiver sensitivity.

Calculation:

1. Rearrange the formula from question 1:
 - Path loss (dB) = Transmitted power (dBm) - Received power (dBm)
2. Substitute the values:
 - Path loss (dB) = $13 \text{ dBm} - (-80 \text{ dBm}) = 93 \text{ dB}$
3. Refer to the path loss model provided in your reference book (e.g., Friis transmission formula) and solve for the distance that corresponds to a path loss of 93 dB.

Note: Solving for distance using path loss models can be complex and requires specific details about the environment. Your reference book should provide guidance on using the chosen model.

3. **Data Rate:**

Formula: Data rate (Mbps) = Channel bandwidth (MHz) * Modulation coding rate * Coding efficiency

Values:

- Channel bandwidth (MHz) = 80 MHz
- Modulation coding rate (from reference book): 256-QAM = 8 bits/symbol

- Coding efficiency (from reference book): Depends on the specific 802.11ac mode (e.g., LDPC coding might have an efficiency of 0.8)

Calculation:

1. Look up the coding efficiency for the specific 802.11ac mode from your reference book. Let's assume an efficiency of 0.8 here.
2. Substitute the values:
 - $\text{Data rate} = 80 \text{ MHz} * 8 \text{ bits/symbol} * 0.8 = 512 \text{ Mbps}$

Therefore, the theoretical maximum data rate for this network is 512 Mbps.

Note: This is the theoretical maximum under ideal conditions. Actual data rates will be lower due to factors like interference, network congestion, and overhead.

Scenario: A WiFi network operates in the 5 GHz band using the 802.11ac standard. The network transmits data at a rate of 866 Mbps. Each WiFi packet has a fixed header size of 28 bytes and a variable payload size.

Questions:

1. **Transmission Time Calculation:** How long does it take to transmit a WiFi packet with a payload size of 1024 bytes?
2. **Maximum Throughput Calculation:** If the network experiences a 10% packet loss rate, what is the maximum achievable throughput of the network?
3. **Channel Utilization Calculation:** The network uses a channel with a bandwidth of 80 MHz. What is the channel utilization if the average time between packet transmissions is 2 milliseconds (ms)?

Solutions:

1. Transmission Time Calculation:

- **Formula:** $\text{Transmission time (seconds)} = (\text{Packet size (bytes)} + \text{Header size (bytes)}) / \text{Data rate (Mbps)} / 8 \text{ (conversion to seconds)}$
- **Values:**
 - Packet size = 1024 bytes
 - Header size = 28 bytes
 - Data rate = 866 Mbps = $866 * 10^6 \text{ bits/s}$
- **Calculation:**
 - $\text{Transmission time} = (1024 \text{ bytes} + 28 \text{ bytes}) / (866 * 10^6 \text{ bits/s}) / 8$ (conversion to seconds)
 - $\text{Transmission time} \approx 1.23 \text{ microseconds } (\mu\text{s})$

2. Maximum Throughput Calculation:

- **Formula:** Maximum throughput (Mbps) = Data rate (Mbps) * (1 - Packet loss rate)
- **Values:**
 - Data rate = 866 Mbps
 - Packet loss rate = 10% = 0.1
- **Calculation:**
 - Maximum throughput = 866 Mbps * (1 - 0.1)
 - Maximum throughput = 780.4 Mbps

3. Channel Utilization Calculation:

- **Formula:** Channel utilization (%) = (Packet transmission time (ms) / Average time between packets (ms)) * 100
- **Values:**
 - Packet transmission time = 1.23 μ s (converted to ms: $1.23 * 10^{-3}$ ms)
 - Average time between packets = 2 ms
- **Calculation:**
 - Channel utilization = $(1.23 * 10^{-3} \text{ ms} / 2 \text{ ms}) * 100$
 - Channel utilization $\approx 0.062\%$

Note:

- These are theoretical calculations and actual values may differ based on real-world factors like network congestion, interference, and other protocols overhead.
- The channel utilization is very low in this example. In practice, networks aim for a higher channel utilization for efficient use of the available bandwidth.

1. Signal Strength Calculation:

Scenario: A WiFi router transmits at a power of 20 dBm and the signal strength is measured to be -60 dBm at a distance of 10 meters. What is the path loss in decibels (dB)?

Formula: Path loss (dB) = Transmitted power (dBm) - Received power (dBm)

Values:

- Transmitted power (dBm) = 20 dBm
- Received power (dBm) = -60 dBm

Calculation:

- Path loss = 20 dBm - (-60 dBm) = 80 dB

Therefore, the path loss is 80 dB.

2. Data Rate Calculation:

Scenario: A WiFi network operates on the 5 GHz band using 802.11ac standard with 64-QAM modulation. The channel width is 80 MHz. What is the maximum theoretical data rate achievable in this network?

Formula: Data rate (Mbps) = Channel bandwidth (MHz) * Modulation coding rate * Coding efficiency

Values:

- Channel bandwidth = 80 MHz
- Modulation coding rate (64-QAM) = 6 bits/symbol
- Coding efficiency (802.11ac) ≈ 0.88 (approximate value)

Calculation:

- Data rate = 80 MHz * 6 bits/symbol * 0.88 = 422.4 Mbps (approximately)

Therefore, the maximum theoretical data rate is approximately 422.4 Mbps.

3. Network Capacity Calculation:

Scenario: A WiFi access point can handle a maximum of 250 concurrent users. Each user is estimated to consume an average bandwidth of 10 Mbps for web browsing. What is the maximum total available bandwidth for users if the access point is at full capacity?

Formula: Total available bandwidth (Mbps) = Number of users * Average bandwidth per user

Values:

- Number of users = 250
- Average bandwidth per user = 10 Mbps

Calculation:

- Total available bandwidth = 250 users * 10 Mbps/user = 2500 Mbps

Therefore, the maximum total available bandwidth for users is 2500 Mbps.

Note: These are theoretical calculations and actual performance can vary depending on various factors like interference, network congestion, and user activity.

Numerical questions on Bluetooth protocol with solutions:

1. Data Rate Calculation:

Scenario: A Bluetooth device uses Bluetooth Low Energy (BLE) with a symbol rate of 1 Mbps and QPSK modulation. Each symbol represents 2 bits of data. What is the effective data rate in bits per second?

Formula: Data rate (bits/s) = Symbol rate (symbols/s) * Bits per symbol

Values:

- Symbol rate = 1 Mbps = 1,000,000 symbols/s
- QPSK modulation = 2 bits per symbol

Calculation:

- Data rate = 1,000,000 symbols/s * 2 bits/symbol = 2,000,000 bits/s

Therefore, the effective data rate is 2,000,000 bits per second.

2. Transmission Time Calculation:

Scenario: A BLE device needs to transmit a data packet of 20 bytes. The data rate is 1 Mbps as calculated in question 1. How long does it take to transmit the packet in milliseconds?

Formula: Transmission time (ms) = Packet size (bytes) * 8 bits/byte / Data rate (bits/s) * 1000 ms/s

Values:

- Packet size = 20 bytes
- Data rate = 2,000,000 bits/s

Calculation:

- Transmission time = 20 bytes * 8 bits/byte / 2,000,000 bits/s * 1000 ms/s = 8 milliseconds

Therefore, it takes 8 milliseconds to transmit the packet.

3. Range Calculation (Assuming Free Space Path Loss Model):

Scenario: A Bluetooth device transmits at a power of 0 dBm and the minimum acceptable received power for reliable communication is -80 dBm. What is the maximum theoretical range of the device in meters, assuming free space path loss?

Formula: $\text{Distance (m)} = \sqrt{(P_t * G_t * G_r * \lambda^2) / (4 * \pi * P_r)}$

Values:

- Transmitted power (P_t) = 0 dBm = 1 mW
- Minimum acceptable received power (P_r) = -80 dBm = 10^{-8} W
- Reference book might provide values for antenna gains (G_t and G_r) and wavelength (λ)
- Assuming typical values: $G_t = G_r = 1$ (unity gain), $\lambda = 12$ cm (2.4 GHz frequency)

Calculation:

1. Substitute the values: $\text{Distance} = \sqrt{(1 \text{ mW} * 1 * 1 * (0.12 \text{ m})^2) / (4 * \pi * 10^{-8} \text{ W})}$
2. Solve the equation using a calculator: Distance \approx 10 meters

Therefore, the maximum theoretical range is approximately 10 meters, but note this assumes an ideal environment with no obstacles. In real-world scenarios, the range will be significantly lower due to various factors.

4. Connection Management:

Scenario: A Bluetooth device can support up to 7 active connections simultaneously. How many total devices can connect to it, considering parked connections?

Concept: Bluetooth distinguishes between active and parked connections. Active connections are those actively exchanging data, while parked connections are devices previously connected that can be quickly reconnected without re-pairing.

Explanation: While the device can only support 7 active connections at once, the total number of devices it can connect to is higher due to parked connections.

Answer: The number of total connectable devices depends on the specific Bluetooth implementation and may not be explicitly stated. However, it is generally higher than 7, accommodating parked connections in addition to the active ones.

These are some numerical questions and solutions related to Bluetooth protocol. Remember that actual performance and range might vary depending on specific

devices, environments, and interference levels. Refer to the relevant specifications and documentation for your specific Bluetooth devices.

1. Data Rate Calculation:

Scenario: A Bluetooth device uses Bluetooth Low Energy (BLE) with 1 Mbps PHY (physical layer) and Coded PHY with a coding rate of 2/3. What is the effective data rate in kilobits per second (kbps)?

Formula: Data rate (kbps) = PHY rate (Mbps) * Coding rate

Values:

- PHY rate = 1 Mbps
- Coding rate = 2/3

Calculation:

- Data rate = 1 Mbps * (2/3) = 2/3 Mbps
- Convert Mbps to kbps by multiplying by 1000:
 - Data rate = (2/3 Mbps) * (1000 kbps/Mbps) ≈ 667 kbps

Therefore, the effective data rate is approximately 667 kbps.

2. Range Estimation:

Scenario: A Bluetooth device transmits at a power of 0 dBm and the minimum received power level for reliable communication is -90 dBm. What is the estimated range of the Bluetooth device, assuming free space path loss model?

Formula: Path loss (dB) = $10 * \log_{10} \left(\frac{4 * \pi * d^2}{P_t * G_t * G_r * \lambda^2} \right)$

Values:

- Minimum received power (P_r) = -90 dBm
- Transmitted power (P_t) = 0 dBm
- Assuming reference values: $G_t = G_r = 1$ (unity gain), $\lambda = 12$ cm (2.4 GHz frequency)

Steps:

1. Rearrange the formula to solve for distance (d): $d = \sqrt{\frac{P_t * G_t * G_r * \lambda^2}{10^{(\text{Path loss}/10)} * 4 * \pi}}$
2. Substitute the values and solve for d: $d = \sqrt{\frac{10^{(0/10)} * 1 * 1 * (0.12)^2}{10^{(-90/10)} * 4 * \pi}}$) $d \approx 10$ meters

Therefore, the estimated range of the Bluetooth device is approximately 10 meters.

Note: This is an estimate based on the free space path loss model, which might not be accurate for real-world scenarios with obstacles.

3. Connection Management:

Scenario: A Bluetooth device can manage up to 7 active connections in a piconet (personal area network). How many Bluetooth devices can theoretically be connected simultaneously in a scatternet (network consisting of multiple piconets)?

Concept: In a scatternet, multiple devices can act as both masters and slaves, allowing for more complex connections than a single piconet.

Answer: While a scatternet allows for more complex connections, the maximum number of **simultaneous connections** for a single device still remains **limited by the number of active connections it can manage**.

Therefore, in a scatternet, a single device can still only have **up to 7 simultaneous connections** even though it might be able to participate in multiple piconets at the same time.

1. Data Rate Calculation:

Scenario: A Bluetooth device uses Bluetooth Low Energy (BLE) with a symbol rate of 1 Mbps and QPSK modulation. Each symbol represents 2 bits of data. What is the effective data rate in bits per second?

Formula: Data rate (bits/s) = Symbol rate (symbols/s) * Bits per symbol

Values:

- Symbol rate = 1 Mbps = 1,000,000 symbols/s
- QPSK modulation = 2 bits per symbol

Calculation:

- Data rate = 1,000,000 symbols/s * 2 bits/symbol = 2,000,000 bits/s

Therefore, the effective data rate is 2,000,000 bits per second.

2. Range Estimation:

Scenario: A Bluetooth device transmits at a power of 0 dBm and the minimum received signal strength for reliable communication is -80 dBm. Assuming free space path loss model, what is the estimated maximum range of the device?

Formula: Path loss (dB) = $10 * \log_{10} \left(\frac{(4 * \pi * d)^2}{P_t * G_t * G_r * \lambda^2} \right)$

Values:

- Transmitted power (P_t) = 0 dBm = 1 mW
- Minimum received signal power (dBm) = -80 dBm = 10^{-8} W
- Assuming typical values for antenna gains (G_t and G_r) = 1 (unity gain)
- Wavelength (λ) for Bluetooth \approx 12 cm (2.4 GHz frequency)

Calculation:

1. Rearrange the formula to solve for distance (d): $d = \sqrt{\frac{(P_t * G_t * G_r * \lambda^2)}{(10^{(\text{Path loss} / 10)}) * (4 * \pi)}}$
2. Substitute the values: $d = \sqrt{\frac{(1 \text{ mW} * 1 * 1 * (0.12 \text{ m})^2)}{(10^{((-80) / 10)}) * (4 * \pi)}}$
3. Solve the equation using a calculator: $d \approx 10$ meters (approximately)

Therefore, the estimated maximum range of the device is 10 meters.

Note: This is an estimate using the free space path loss model, which might not be accurate for real-world environments with obstacles.

3. Connection Management:

Scenario: A Bluetooth device can manage up to 7 active connections simultaneously. How many total devices can be connected to the device if only 3 connections are actively transmitting data at a time?

Concept: Bluetooth uses a master-slave architecture. While a device can theoretically connect to 7 devices total, only one slave device can actively transmit data to the master at a time.

Calculation:

- The master device itself doesn't participate in active data transmission.
- Therefore, the remaining 6 connected devices can be categorized:
 - 3 devices actively transmitting data (slaves).
 - 3 devices connected but not actively transmitting (slaves in standby mode).

Therefore, a total of 7 devices can be connected to the Bluetooth device, even with only 3 active data transmissions at a time.

4. Security Mode Selection:

Scenario: A user wants to choose a security mode for a Bluetooth connection between a phone and a smartwatch. The user prioritizes security over connection speed. Which mode would be most suitable?

Options:

- **BR/EDR (Basic Rate/Enhanced Data Rate):** Offers low security and high speed.
- **LE Security Mode 1:** Offers medium security and medium speed.
- **LE Security Mode 2:** Offers high security and low speed.

Solution:

- Considering the user prioritizes security, **LE Security Mode 2** is the most suitable option as it offers the highest level of security among the available choices.

These are just a few examples, and the specific types of numerical problems related to Bluetooth will depend on the specific topics you're interested in.
